### Heavy-flavour production

Estimation of  $\gamma$ ,  $\pi^0$  and  $\eta$  ratios in the photonic background in proton-proton collisions at  $\sqrt{s}=7$  TeV with ALICE

#### Fabrizio Grosa

GSI Summer Student Program 2014

#### **Outline**

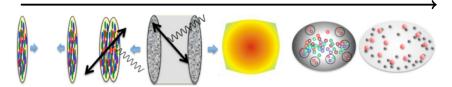

- Heavy-flavour production in heavy-ion collisions
- Photonic background
- Results and outlook

## Quark-gluon plasma

 QCD predicts that under extreme conditions of very high temperature or energy densities, hadronic matter transit to a deconfined phase of matter called "quark-gluon plasma" (QGP)

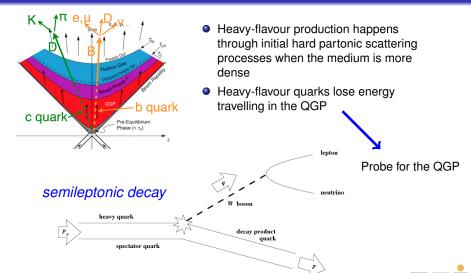

- Collision: large number of hard scatterings between partons.
- Thermalization: the thermal equilibrium is reached.
- QGP: the fireball is created, in which quarks and gluons are free.

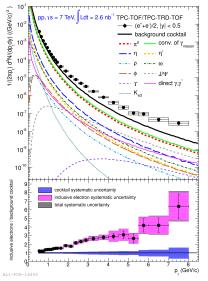

- Hadronization: the quarks and the glouns are recombined in hadrons.
- Chemical freeze-out: inelastic scattering cease.
- Kinetic freeze-out : elastic scattering cease.

## Heavy-flavour production

# Background of heavy-flavour hadron decays

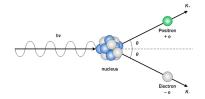

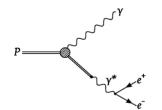

- There are other sources of leptons which form the background for the heavy-flavour hadron semileptonic decay.
- The inclusive electrons and positrons are all the  $e^{\pm}$  measured. which are decay products of both hadrons carrying heavy quarks, and the background sources.
- After the subtraction of the background only the remaining  $p_T$ spectrum contains electrons from heavy-flavour hadron decays only.

### Main sources of the photonic background

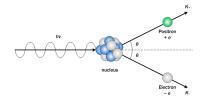

• Photon conversion:  $\gamma \rightarrow e^+e^-$ 

• Dalitz decays:  $\pi^0 
ightarrow e^+ e^- \gamma \ \eta 
ightarrow e^+ e^- \gamma \ \eta' 
ightarrow e^+ e^- \gamma \ \omega 
ightarrow e^+ e^- \pi_0 \ \Phi 
ightarrow e^+ e^- \eta$ 

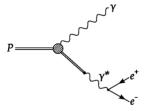

## Main sources of the photonic background

ullet Photon conversion:  $\gamma 
ightarrow e^+e^-$ 

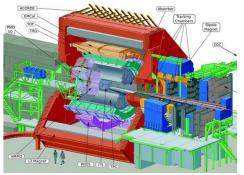

Dalitz decays:

$$\pi^0 
ightarrow e^+ e^- \gamma \ \eta 
ightarrow e^+ e^- \gamma \ \eta' 
ightarrow e^+ e^- \gamma \ \omega 
ightarrow e^+ e^- \pi_0 \ \phi 
ightarrow e^+ e^- \eta$$

The aim of this study is to calculate the ratio between photon conversions and Dalitz decays in the photonic background

#### The ALICE detector

 ALICE is the experiment at LHC dedicated to heavy-ion collisions

- Inner Tracking System: first sub detector reached by the particles originating in the primary vertex
- Time Projection Chamber: the main tracking detector

#### Data samples

- simulated proton-proton collision events at  $\sqrt{s} = 7 \, TeV$ 
  - decayed with Pythia 6
  - propagation through detectors described with *GEometry* ANd Tracking 3
  - tracks reconstructed with AliROOT
- this study is focused on proton-proton collisions because they are the reference system for the Pb-Pb collisions

Associated e<sup>±</sup>

#### $e^{\pm}$ identification

dN/dP<sub>T</sub> (c/GeV)

10<sup>3</sup>

 $10^{2}$ 

• Inclusive  $e^{\pm}$   $\longrightarrow$  stringent cuts are required • Associated  $e^{\pm}$   $\longrightarrow$  required • Inclusive  $e^{\pm}$ 

P<sub>⊤</sub> (GeV/c)

relaxed cuts are required: tracks resolution is lost, but efficiency is maximised

Finally, using the MC truth information, only the tracks that really belong to  $e^\pm$  are selected

## Invariant mass analysis

According to Special Relativity the four-momentum  $p = (E, \vec{p})$  of a physics system is always conserved, and the mass of a particle is equal to:

$$m_i^2 = E_i^2 - \vec{p_i}^2 \equiv p_i^2$$

we can calculate the invariant mass of a particle from its decay products

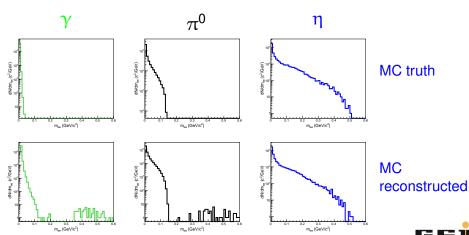

$$m_{ee} = \sqrt{(\rho_1 + \rho_2)^2} = \sqrt{(E_1 + E_2)^2 - (\vec{\rho_1} + \vec{\rho_2})^2}$$

#### Invariant mass distributions from MC truth

Using the MC truth information is possible to know the mother particle of every  $e^+e^-$  pair  $\longrightarrow$  obtained the invariant mass distribution of each source

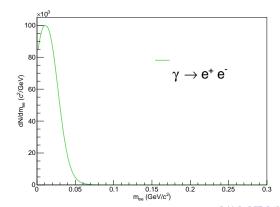

## Distribution for photons

• For the photon conversion ———— exponentially modified Gaussian distribution:

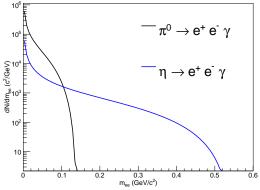

$$\frac{dN}{dm_{ee}} = N_{\gamma} \cdot e^{-\frac{(m_{ee} - M_{\gamma})^2}{2\sigma^2}} + \Theta(m_{ee} - M_{\gamma}) e^{\frac{m_{ee} - M_{\gamma}}{\tau}}$$

#### Kroll-Wada distribution

$$\frac{dN}{dm_{ee}} = N_X \cdot \frac{2}{m_{ee}} \left\{ (1 + (m_{ee}/M_X)^2)^2 - 4(m_{ee}/M_X)^2 \right\}^{3/2} \sqrt{1 - \frac{4(m_e/M_X)^2}{(m_{ee}/M_X)^2}} \cdot \left\{ 1 + \frac{2(m_e/M_X)^2}{(m_{ee}/M_X)^2} \right\} \cdot F_X(m_{ee}^2)^2 + \frac{2(m_e/M_X)^2}{(m_{ee}/M_X)^2} \cdot \left\{ 1 + \frac{2(m_e/M_X)^2}{(m_{ee}/M_X)^2} \right\} \cdot F_X(m_{ee}^2)^2 + \frac{2(m_e/M_X)^2}{(m_{ee}/M_X)^2} \cdot \left\{ 1 + \frac{2(m_e/M_X)^2}{(m_{ee}/M_X)^2} \right\} \cdot F_X(m_{ee}^2)^2 + \frac{2(m_e/M_X)^2}{(m_{ee}/M_X)^2} \cdot \left\{ 1 + \frac{2(m_e/M_X)^2}{(m_{ee}/M_X)^2} \right\} \cdot F_X(m_{ee}^2)^2 + \frac{2(m_e/M_X)^2}{(m_{ee}/M_X)^2} \cdot \left\{ 1 + \frac{2(m_e/M_X)^2}{(m_{ee}/M_X)^2} \right\} \cdot F_X(m_{ee}^2)^2 + \frac{2(m_e/M_X)^2}{(m_{ee}/M_X)^2} \cdot \left\{ 1 + \frac{2(m_e/M_X)^2}{(m_{ee}/M_X)^2} \right\} \cdot F_X(m_{ee}^2)^2 + \frac{2(m_e/M_X)^2}{(m_{ee}/M_X)^2} \cdot \left\{ 1 + \frac{2(m_e/M_X)^2}{(m_{ee}/M_X)^2} \right\} \cdot F_X(m_{ee}^2)^2 + \frac{2(m_e/M_X)^2}{(m_{ee}/M_X)^2} \cdot \left\{ 1 + \frac{2(m_e/M_X)^2}{(m_{ee}/M_X)^2} \right\} \cdot F_X(m_{ee}^2)^2 + \frac{2(m_e/M_X)^2}{(m_{ee}/M_X)^2} \cdot \left\{ 1 + \frac{2(m_e/M_X)^2}{(m_{ee}/M_X)^2} \right\} \cdot F_X(m_{ee}^2)^2 + \frac{2(m_e/M_X)^2}{(m_{ee}/M_X)^2} \cdot \left\{ 1 + \frac{2(m_e/M_X)^2}{(m_{ee}/M_X)^2} \right\} \cdot F_X(m_{ee}^2)^2 + \frac{2(m_e/M_X)^2}{(m_{ee}/M_X)^2} \cdot \left\{ 1 + \frac{2(m_e/M_X)^2}{(m_{ee}/M_X)^2} \right\} \cdot F_X(m_{ee}^2)^2 + \frac{2(m_e/M_X)^2}{(m_e/M_X)^2} \cdot \left\{ 1 + \frac{2(m_e/M_X)^2}{(m_e/M_X)^2} \right\} \cdot F_X(m_{ee}^2)^2 + \frac{2(m_e/M_X)^2}{(m_e/M_X)^2} \cdot \left\{ 1 + \frac{2(m_e/M_X)^2}{(m_e/M_X)^2} \right\} \cdot F_X(m_{ee}^2)^2 + \frac{2(m_e/M_X)^2}{(m_e/M_X)^2} \cdot \left\{ 1 + \frac{2(m_e/M_X)^2}{(m_e/M_X)^2} \right\} \cdot F_X(m_{ee}^2)^2 + \frac{2(m_e/M_X)^2}{(m_e/M_X)^2} \cdot \left\{ 1 + \frac{2(m_e/M_X)^2}{(m_e/M_X)^2} \right\} \cdot F_X(m_{ee}^2)^2 + \frac{2(m_e/M_X)^2}{(m_e/M_X)^2} \cdot \left\{ 1 + \frac{2(m_e/M_X)^2}{(m_e/M_X)^2} \right\} \cdot F_X(m_{ee}^2)^2 + \frac{2(m_e/M_X)^2}{(m_e/M_X)^2} \cdot \left\{ 1 + \frac{2(m_e/M_X)^2}{(m_e/M_X)^2} \right\} \cdot F_X(m_{ee}^2)^2 + \frac{2(m_e/M_X)^2}{(m_e/M_X)^2} \cdot \left\{ 1 + \frac{2(m_e/M_X)^2}{(m_e/M_X)^2} \right\} \cdot F_X(m_e/M_X)^2 + \frac{2(m_e/M_X)^2}{(m_e/M_X)^2} \cdot \left\{ 1 + \frac{2(m_e/M_X)^2}{(m_e/M_X)^2} \right\} \cdot F_X(m_e/M_X)^2 + \frac{2(m_e/M_X)^2}{(m_e/M_X)^2} \cdot \left\{ 1 + \frac{2(m_e/M_X)^2}{(m_e/M_X)^2} \right\} \cdot F_X(m_e/M_X)^2 + \frac{2(m_e/M_X)^2}{(m_e/M_X)^2} \cdot \left\{ 1 + \frac{2(m_e/M_X)^2}{(m_e/M_X)^2} \right\} \cdot F_X(m_e/M_X)^$$

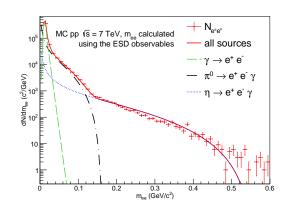

where  $\left\{ \begin{array}{l} F_{\pi^0}(m_{\rm ee}^2) = \frac{1}{(1-5.5 \cdot m_{\rm ee}^2)^2} \\ F_{\eta}(m_{\rm ee}^2) = \frac{1}{(1-1.9 \cdot m_{\rm ee}^2)^2} \end{array} \right.$ 

#### Fit template

- Select  $e^+e^-$  pair with same  $\gamma$ ,  $\pi^0$  or  $\eta$  mother particle from MC truth
- Calculate their invariant mass and obtain the relative distribution
- Fit with the function which is the sum of the three contributions.

#### From MC truth

number of γ	$418300\pm600$
number of $\pi^0$	$362000 \pm 600$
number of η	42100 ± 200
$n_{\gamma}/n_{\pi^0}$	$1.156 \pm 0.003$
$n_{\gamma}/n_{\eta}$	$9.94 \pm 0.05$
$n_{\gamma}/(n_{\pi^0}+n_{\eta})$	$1.035 \pm 0.002$

#### From the Fit

$M_{\gamma}$	0.01107 ± 0.00018 GeV/d	
$M_{\pi^0}$	0.1611 ± 0.0003 GeV/c <sup>2</sup>	
$M_{\eta}$	0.558 ± 0.004 GeV/c <sup>2</sup>	
Integral of $\gamma$	418300 ± 1100	
Integral of $\pi^0$	355000 ± 2000	
Integral of η	49200 ± 600	
$I_{\gamma}/I_{\pi^0}$	1.179 ± 0.007	
$I_{\gamma}/I_{\eta}$	8.50 ± 0.11	
$I_{\gamma}/(I_{\pi^0} + I_{\eta})$	1.035 ± 0.006	

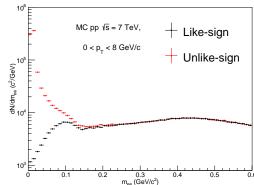

# Like-sign and Unlike-sign distributions

- Unlike-sign distribution
- $\longrightarrow$  inclusive  $e^{\pm}$  + associated  $e^{\mp}$ 
  - photonic signal + combinatorial background

- Like-sign distribution
  - $\longrightarrow$  inclusive  $e^{\pm}$  + associated  $e^{\pm}$ 
    - ----> combinatorial background

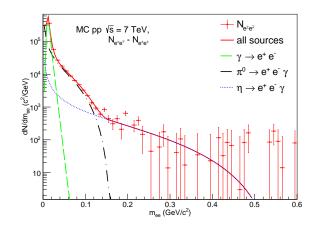

Photonic background

## Fit of the photonic background

• The like-sign distribution is subtracted to the unlike-sign distribution

 The resulting photonic signal is fitted with the template obtained from the MC truth

Integral of $\gamma$	$423000 \pm 6000$
Integral of $\pi^0$	$354000 \pm 4000$
Integral of η	$42000 \pm 3000$
$I_{\gamma}/I_{\pi^0}$	$1.19 \pm 0.02$
$I_{\gamma}/I_{\eta}$	$10.0\pm0.8$
$J_{\nu}/(J_{-0} + J_{0})$	1.07 + 0.02

#### Results

Particle	Number from MC truth	Relative statistical error	Integral from photonic signal fit	Relative statistical error
γ	418300 ± 600	0.14%	423000 $\pm$ 6000	1.4%
$\pi^0$	362000 ± 600	0.17%	$354000 \pm 4000$	1.1%
η	42100 ± 200	0.48%	$42000 \pm 3000$	7.1%

Ratios	MC truth	Photonic signal fit	Gaussian test (num of $\sigma$ )
$\gamma/\pi^0$	$1.156 \pm 0.003$	1.19 ± 0.02	1.68
γ/η	9.94 ± 0.05	$10.0\pm0.8$	0.07
$\gamma/(\pi^0 + \eta)$	$1.035 \pm 0.002$	$1.07 \pm 0.02$	1.73

#### Results

## pp and Pb-Pb data

- look into proton-proton data and verify that the same ratios are found
- Pb-Pb events: What would be different?

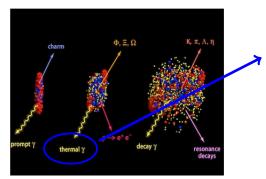

## pp and Pb-Pb data

- look into proton-proton data and verify that the same ratios are found
- Pb-Pb events : What would be different?

An excess of  $\gamma$ , due to the thermal photons generated by the fireball, is expected

the ratio between gamma conversion and Dalitz decavs should be larger
